### ABSTRACT

**Background:** <sup>99m</sup>Tc-Sestamibi Single Photon Emission Computed Tomography/Computed Tomography (SPECT/CT) contributes to the non-invasive differentiation of renal oncocytoma (RO) from renal cell carcinoma (RCC) by characterising renal tumours as Sestamibi positive or Sestamibi negative regarding their <sup>99m</sup>Tc-Sestamibi uptake compared to the non-tumoral renal parenchyma.

**Purpose:** To determine whether <sup>99m</sup>Tc-Sestamibi uptake in renal tumour and the non-tumoral renal parenchyma measured using Standard Uptake Value (SUV) SPECT, has a beneficial role in differentiating RO from RCC.

**Material and Methods:** Fifty-seven renal tumours from 52 patients were evaluated. In addition to visual evaluation of <sup>99m</sup>Tc-Sestamibi uptake, SUV<sub>max</sub> measurements were performed in the renal tumour and the ipsilateral non-tumoral renal parenchyma. Analysis of the area under the receiver operating characteristic curve identified an optimal cut-off value for detecting RO, based on the relative ratio of <sup>99m</sup>Tc-Sestamibi uptake.

**Results:** Semiquantitative evaluation of <sup>99m</sup>Tc-Sestamibi uptake did not improve the performance of <sup>99m</sup>Tc-Sestamibi SPECT/CT in detecting RO. <sup>99m</sup>Tc-Sestamibi SPECT/CT identifies a group of mostly indolent Sestamibi-positive tumours with low malignant potential containing RO, Low-Grade Oncocytic Tumours, Hybrid Oncocytic Tumours, and a subset of chromophobe RCCs.

**Conclusion:** The imaging limitations for accurate differentiation of Sestamibi-positive renal tumours mirror the recognised diagnostic complexities of the histopathologic evaluation of oncocytic neoplasia. Patients with Sestamibi-positive renal tumours could be better suited for biopsy and follow-up, according to the current active surveillance protocols.

## Introduction

Benign and malignant solid renal tumours overlap in their standard imaging features [1]. The inability to accurately diagnose benign renal neoplasia results in up to 30% of unnecessary partial nephrectomies [2]. Currently, it is not possible to preoperatively differentiate between different types of solid renal tumours using the existing molecular imaging techniques [3,4]. The introduction of <sup>99m</sup>Tc-Sestamibi single photon emission computed tomography/computed tomography (SPECT/CT) improves the characterisation and the distinction of solid renal tumours, as demonstrated in the recent meta-analysis by Wilson et al. [5].

<sup>99m</sup>Tc-Sestamibi SPECT/CT, followed by renal biopsy, improved the management of benign kidney tumours, such as renal oncocytoma (RO), by reducing unnecessary surgeries [6] and by introducing cost-saving efficiencies compared with the established clinical routines [7].

Histopathological and molecular characterisation of renal neoplasms is continuously evolving, as reflected in the 2016 and 2022 World Health Organization (WHO) classification by introducing new, provisional and emerging renal entities [8–10]. For example, clear cell papillary RCC (ccpRCC), a tumour of low malignant potential, is now classified as a separate entity [11]. The so-called “hybrid chromophobe

oncocyctic tumour" (HOCT), showing features that overlap between RO and chromophobe renal cell carcinoma (chRCC), considered a subtype of chRCC in the 2016 WHO classification, has been found to demonstrate a molecularly variable profile, with genomic features intermediate between RO and chRCC [12]. Other provisional and emerging entities, such as low-grade oncocyctic tumour (LOT) and eosinophilic vacuolated tumour (EVT), are also expanding the spectrum of renal oncocyctic neoplasia [13]; both entities have been recently listed in the 2022 5<sup>th</sup> edition of WHO classification as "emerging renal entities" [10]. For example, LOT is an indolent, typically sporadic and solitary tumour [14]; rare cases have been documented in tuberous sclerosis complex (TSC) patients [15,16]. Although it has some similar morphologic features to RO and chRCC, it also has some differences and an unusual CK7 positive/CD117 negative immunoprofile [17]. Recent studies have found frequent *TSC/MTOR* mutations in LOT, but a uniform lack of multiple chromosomal losses, as seen in chRCC, has not been found [15,16].

Prior studies have published findings regarding the visual differentiation of RO from RCC utilising <sup>99m</sup>Tc-Sestamibi SPECT/CT [18] in line with the previous findings by Gorin et al. [19]. According to the initial hypothesis of Rowe et al. [20], renal tumours, such as RO that demonstrate greater mitochondrial content, exhibit an increased uptake of <sup>99m</sup>Tc-Sestamibi, given that Sestamibi acts as a mitochondrial agent. Therefore, renal tumours with increased <sup>99m</sup>Tc-Sestamibi uptake can be characterised as 'Sestamibi-positive'. In contrast, renal tumours with decreased <sup>99m</sup>Tc-Sestamibi uptake can be considered 'Sestamibi-negative'.

In the present study, we sought to evaluate if implementing additional quantitative tools will aid in the visual assessment of <sup>99m</sup>Tc-Sestamibi SPECT/CT in patients with solid renal tumours and whether this could improve the diagnostic performance in differentiating RO from other RCCs. In particular, we investigated if standardised uptake value (SUV) SPECT could strengthen the preoperative characterisation of solid renal tumours.

## Material and methods

### Study design and image acquisition

This explorative, non-randomised prospective study started in September 2015 [18] and ended in September 2019. All eligible candidates were discussed at the kidney tumour conference in the Radiology Department of Karolinska University Hospital, Huddinge. Patients with T2, T3 or T4 renal tumours, renal tumours > 7 cm in maximum diameter, and/or patients with metastatic disease were not included in the study. Patients who agreed to participate underwent a <sup>99m</sup>Tc-Sestamibi SPECT/CT examination before nephrectomy or renal biopsy, following the same imaging protocol previously described and published by our group [21]. In brief, a CT scan was performed after a SPECT acquisition with projections reconstructed using Hermes SUV SPECT Hybrid Recon™ Oncology software (v.1.2) (HERMES Medical Solutions AB, Stockholm, Sweden). To enable quantitative evaluation, we collected the available data on syringe activity before administration, syringe residual activity post-administration, patient

weight, time points of injection, and scan start, all used in the reconstruction software.

### Evaluation of <sup>99m</sup>Tc-Sestamibi SPECT/CT examination

Two readers independently and simultaneously performed the visual evaluation: a Consultant in Radiology and Nuclear Medicine and a Consultant in Radiology. To mitigate the effects of interobserver variation, we redefined the uptake of <sup>99m</sup>Tc-Sestamibi in the examined renal tumour as follows: a tumour was classified as Sestamibi-positive if the <sup>99m</sup>Tc-Sestamibi uptake was visually higher compared to the ipsilateral normal renal parenchyma. If the <sup>99m</sup>Tc-Sestamibi uptake in the tumour was visually equal to or lower than the ipsilateral renal parenchyma, the tumour was classified as a Sestamibi-negative. In cases with a disagreement between the readers, a third reader was added, and all three independently performed a blind re-evaluation of these cases.

The two main readers also performed SUV<sub>mean</sub> and SUV<sub>max</sub> measurements in the renal tumour, as well as assessed the ipsilateral non-tumoral renal parenchyma. Freehand regions of interest (ROIs) of complete tumours were drawn in the axial CT images of the SPECT/CT examination. Volumes of interest (VOIs) were automatically generated based on the manually drawn ROIs. The VOIs were copied onto the SPECT images, and the SUV parameters were annotated. To obtain SUV<sub>mean</sub> and SUV<sub>max</sub> values, fixed 1 cm<sup>3</sup> VOIs spheres were similarly placed in the regions of high renal <sup>99m</sup>Tc-Sestamibi uptake in the ipsilateral non-tumoral renal parenchyma. We excluded the SUV<sub>peak</sub> measurements because many renal tumours were too small (volume approximately 1 cm<sup>3</sup> or less) to be evaluated using this parameter because, by definition, SUV<sub>peak</sub> represents the maximum activity concentration in 1 cm<sup>3</sup> volume.

### Histopathological analysis of <sup>99m</sup>Tc-Sestamibi SPECT/CT examined renal tumours & immunohistochemical investigation of renal oncocyctic tumours

In cooperation with the Clinical Pathology-Cytology Department of our hospital, the diagnostic tissue material of the study (i.e. surgical resections and/or biopsies) was re-evaluated. Two Consultant Pathologists independently and simultaneously reviewed the haematoxylin & eosin (H&E), as well as the immunohistochemical (IHC) slides of all tumours in a blinded manner and without any knowledge of the prior visual or quantitative evaluation of the <sup>99m</sup>Tc-Sestamibi SPECT/CT dataset. The confirmed histopathological diagnoses and/or updated diagnoses, based on consensus, were used as the gold standard to correlate with the results from <sup>99m</sup>Tc-Sestamibi SPECT/CT examinations. A third expert Urologic Pathologist was subsequently asked to blindly evaluate all chRCCs included in this study to further help assess the observed *in situ* metabolomic differences in the Sestamibi-positive versus Sestamibi-negative chRCCs, as demonstrated in our previous study [22].

## Statistical analysis

Intra Class Correlation (ICC) was calculated to assess the intra-reader reliability of  $SUV_{mean}$  and  $SUV_{max}$  SPECT measurements. We calculated the average value of  $SUV_{mean}$  measurements from the two readers per case. The same was done for  $SUV_{max}$ . The ratio of the  $^{99m}Tc$ -Sestamibi uptake (the uptake in the renal tumour/the uptake in the ipsilateral non-tumoral renal parenchyma) was also calculated for each case. To illustrate the trade-off in sensitivity and specificity in detecting RO, we analysed the area under the receiver operating characteristic curve (AUC) to identify an optimal cut-off value based on the relative  $^{99m}Tc$ -Sestamibi uptake. To illustrate the results, each tumour category was designated with a letter (A-J, Supplementary Figure 1).

## Results

In total, 58 renal masses from 52 patients were included in the study between 2015 and 2019; of note, four patients had multiple and/or bilateral renal lesions. Thirty-seven out of 58 (64%) renal tumours were resected with radical or partial nephrectomy, while the remaining 21 (36%) were biopsied (7 ccRCCs, 4 chRCCs, 3 ccprRCCs, 3 RO, 2 pRCCs and 2 HOCTs).

## Histopathological & immunohistochemical assessment

Five renal tumours were re-classified upon re-evaluation by consensus, as follows: 4 RO were re-classified as chRCC and HOCT (2 cases each), while one pRCC (that in our previous pilot study [18] exhibited slightly increased  $^{99m}Tc$ -Sestamibi uptake) was re-classified as chRCC. One tumour initially characterised as HOCT in our previous pilot study [18] actually

**Table 1.** Patient and renal tumour characteristics.

Number of patients	52
Number of renal tumours	57
Size of renal tumours in mm (median [IQR])	24.0 [17.0, 39.0]
Age in years (median, [IQR])	68.0 [60.0, 76.0]
Sex (%)	
Female	19 (33)
Male	38 (67)

Inclusion period September 2015–2019, Karolinska University Hospital, Huddinge. Inclusion criteria: Patients with T1 solid renal tumours, eligible for undergoing surgery or suitable for renal biopsy. Exclusion criteria: T2+ tumours, tumours >7cm in maximum diameter and/or patients with meta-static disease.

mm: millimetres, IQR: interquartile range.

**Table 2.** Visual evaluation of  $^{99m}Tc$ -Sestamibi uptake on 57 solid renal tumours.

Histological types of renal tumours	Number of renal tumours	$^{99m}Tc$ -Sestamibi positive, n (%)	$^{99m}Tc$ -Sestamibi negative, n (%)
Renal oncocytoma	11	9 (82%)	2 (18%)
HOCT	5	5 (100%)	0
Chromophobe RCC	11	6 (55%)	5 (45%)
Clear cell RCC	13	0	13 (100%)
Papillary RCC	9	0	9 (100%)
Clear cell papillary RCC	4	0	4 (100%)
Collision RCC (chRCC – pRCC)	1	0	1 (100%)
B-cell lymphoma	1	0	1 (100%)
Metanephric adenoma	1	0	1 (100%)
Angiomyolipoma	1	0	1 (100%)

The sensitivity of  $^{99m}Tc$ -Sestamibi SPECT/CT examination in detecting renal oncocytoma is estimated at 82%, with a specificity of 76%. RCC: Renal Cell Carcinoma, HOCT: Hybrid Oncocytic Chromophobe Tumour, chRCC: chromophobe RCC, pRCC: papillary RCC.

corresponded to normal renal parenchyma. It was excluded from further analysis, thus reducing the final tumour cohort to 57. The patient and tumour characteristics are presented in Table 1. All amended diagnoses were immediately communicated to the referral urologists for appropriate clinical management and follow-up, whenever necessary. Accordingly, the final diagnoses were established (in decreasing order of frequency) as follows: 13 ccRCCs, 11 chRCCs, 11 RO (one with adjacent) papillary adenoma, 9 pRCCs, 5 HOCTs, 4 clear cells papillary RCCs (1 with adjacent papillary adenoma), 1 “collision tumour” comprising chRCC and pRCC, 1 B cell non-Hodgkin’s (follicular) lymphoma, 1 metanephric adenoma and 1 angiomyolipoma.

## Visual evaluation of $^{99m}Tc$ -Sestamibi SPECT/CT examinations

Agreement on the visual evaluation of  $^{99m}Tc$ -Sestamibi uptake was observed in 51 out of 57 (90%) solid renal tumours. In 6 (10%) cases, the two readers disagreed; however, a complete agreement and a final consensus were reached in all 6 cases when a third reader was included in the assessment (as previously explained). The results of the visual assessment are presented in Table 2, showing 82% sensitivity and 76% specificity in the detection of RO. When clustering RO and HOCT together, the above-mentioned performance of  $^{99m}Tc$ -Sestamibi SPECT/CT reached 88% sensitivity and 85% specificity.

## Quantitative SUV SPECT measurements

Similar to our previous study [21], the ICC for  $SUV_{max}$  and  $SUV_{mean}$  measurements of the examined tumours showed a high agreement between the two readers of 88% and 94%, respectively. Likewise, the ICC between the readers, when measuring SUV SPECT parameters in the ipsilateral non-tumoral renal parenchyma showed moderate agreement, as shown in Table 3.

Analysis of AUC based on the ratio of the relative  $^{99m}Tc$ -Sestamibi uptake was performed by sub-clustering RO as a Sestamibi-positive subgroup. At the same time, all remaining tumour types were considered as a Sestamibi-negative subgroup. Optimal cut-off values for the characterisation of tumours as Sestamibi-positive vs Sestamibi-negative were obtained using the closest-top left criterion. The ratio of relative  $^{99m}Tc$ -Sestamibi uptake based on  $SUV_{max}$  measurements

of the tumour (T) vs non-tumoral renal parenchyma (N) demonstrated better performance (AUC: 0.787 [95% CI: 0.644–0.903]) (Figure 1), when compared to the ratio based on  $SUV_{mean}$  measurements (AUC: 0.686 [95% CI: 0.524–0.830]) (Supplementary Figure 2). The estimated cut-off 0.739 of relative ratio  $^{99m}Tc$ -Sestamibi uptake, based on  $SUV_{max}$  measurements of the renal tumour and the non-tumoral parenchyma, resulted in 64% sensitivity and 83% specificity in detecting RO (AUC: 0.787 [95% CI: 0.644–0.903]).

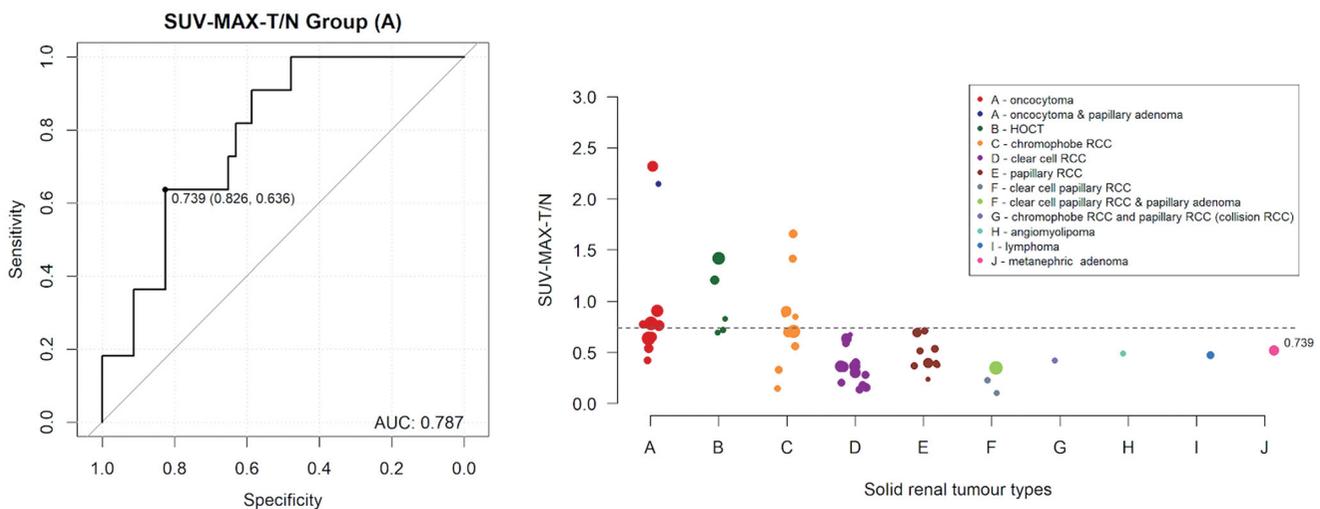

When RO and HOCT are clustered together, the semiquantitative performance of  $^{99m}Tc$ -Sestamibi SPECT/CT reaches 87,5% in sensitivity and 71% in specificity, with an estimated cut-off of 0.61, the relative ratio of  $^{99m}Tc$ -Sestamibi uptake, based on  $SUV_{max}$  measurements of the renal tumour and the non-tumoral parenchyma. The last mentioned cut-off value is comparable with the results from other groups active in this specific field [23] (Supplementary Figure 3).

### Re-evaluation of all chRCCs

An expert Urological Pathologist re-evaluated all chRCCs, resulting in the reclassification of 5 Sestamibi-negative tumours as chRCCs classic type ( $n=4$ ) (Figure 2a–d) and an eosinophilic variant of chRCC ( $n=1$ ). Of the 6 Sestamibi-positive tumours, 3 were re-classified as LOTs (Figure 2e–h), 2 as an eosinophilic variant of chRCC, and 1 as chRCC classic type. However, all these tumours were included in the chRCC subgroup because LOT represents a recently proposed and provisional renal entity recently included in the latest 2022 WHO classification of renal neoplasia [13].

**Table 3.** Intra Class Correlation (ICC) for SUV SPECT measurements between readers on the renal tumour and the non-tumoral renal parenchyma, with a Confidence Interval of 95%.

	$SUV_{max}$	$SUV_{mean}$
Renal tumours	0.877 (0.779–0.930)	0.940 (0.901–0.964)
Non-tumoral renal parenchyma	0.647 (0.467–0.776)	0.683 (0.617–0.800)

**Figure 1.** The ratio of relative  $^{99m}Tc$ -Sestamibi uptake based on  $SUV_{max}$  measurements on the renal tumour (T) and the non-tumoral renal parenchyma (N). The estimated cut-off value of 0.739 of relative ratio  $^{99m}Tc$ -Sestamibi uptake, based on  $SUV_{max}$  measurements of the renal tumour and the non-tumoral parenchyma, resulted in 64% sensitivity and 83% specificity in detecting Renal Oncocytoma (Group A) (AUC: 0.787 [95% CI: 0.644–0.903]). The different colours and sizes of the markers on the right graph represent the different tumour categories and tumour sizes, respectively.

### Discussion

Quantitative evaluation with SUV SPECT measurements performed in HERMES Hybrid Viewer PDR v2.5 did not improve the performance of the  $^{99m}Tc$ -Sestamibi SPECT/CT examination in differentiating RO, a benign renal tumour, from RCC. The well-known intrinsic limitations of SPET/CT [24], for example, the limited spatial resolution and the resulting partial volume effect, may play a crucial role in SUV SPECT measurements due to spill out and/or spill in of the signal from adjacent voxels [25]. Smaller lesions are more affected by the partial volume effect than larger lesions. Uncertainties in SUV SPECT measurements performed on smaller tumours can lead to inaccurate evaluations and the moderate agreement between readers on SUV SPECT measurements performed on non-tumoral renal parenchyma. The implementation of such semiquantitative tools is rather difficult in clinical practice. The aforementioned factors that affect the SUV SPECT measurements can partly explain that no reliable absolute cut-off values in the detection of RO could be found based exclusively on SUV SPECT measurements performed on the different renal tumours. Instead, the relative  $^{99m}Tc$ -Sestamibi uptake between renal tumour and the non-tumoral renal parenchyma is preferred. Another factor contributing to the uncertain SUV SPECT measurements is the interval from the time of  $^{99m}Tc$ -Sestamibi injection and the time of SPECT/CT scan. In this study, this time varied between 60 and 90 min [21], and it has not been studied how much this time difference affects the SUV. This time dependence is well studied as it concerns fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT), but experience in  $^{99m}Tc$ -Sestamibi is limited [24]. The risk that smaller lesions with slight  $^{99m}Tc$ -Sestamibi uptake could be potentially misclassified as Sestamibi-negative due to the above-mentioned spill out of the signal in the adjacent tissues is sustainable also for the visual evaluation of  $^{99m}Tc$ -Sestamibi SPECT/CT examination.

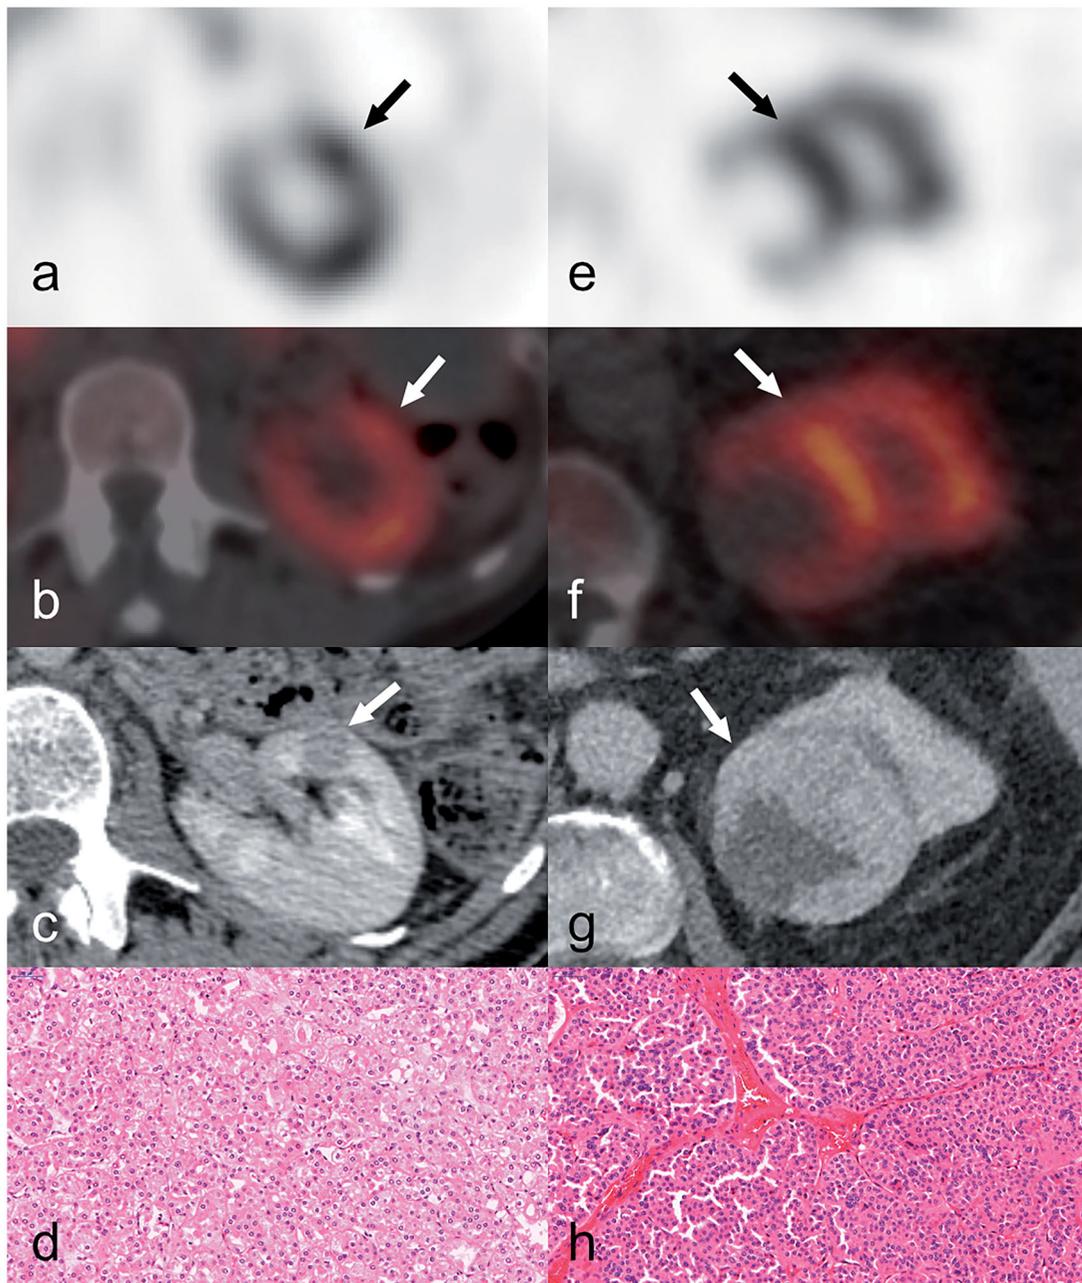

**Figure 2.** A Sestamibi-negative and a Sestamibi-positive chRCC from 2 different patients. *First column, a–d:* (case 42) SPECT axial image (a) indicates the absence of  $^{99m}\text{Tc}$ -Sestamibi in a classic chromophobe RCC located to the dorsal aspect of the left kidney (indicated by arrow). Fused axial SPECT/CT image (b), white arrow indicates the tumour. Preoperative axial CT image (c) in the venous phase, white arrow indicates the tumour. The tumour was characterised as a chRCC (d) upon expert review and was diffusely positive for CK7 (inset; d). *Second column, e–h:* (case 31) SPECT coronal image (e) indicates focal  $^{99m}\text{Tc}$ -Sestamibi uptake in a chromophobe RCC located to the upper pole of the left kidney (indicated by arrow). Fused axial SPECT/CT image (f), white arrow indicates the tumour. Preoperative axial CT image (g) in the venous phase (white arrow indicates the tumour). The tumour (h) was re-characterised as a LOT upon expert review (LOT: low-grade oncocytic tumour) displaying a CK7 positive immunoprofile (inset; h).

In decreasing order of frequency, increased  $^{99m}\text{Tc}$ -Sestamibi uptake compared to the ipsilateral non-tumoral renal parenchyma was visually evident in 5 out of 5 HOCTs (100%), 9 out of 11 RO (82%) (Figure 3), and 6 out of 11 chRCCs (55%). All HOCTs and approximately half of the chRCC cases were classified as Sestamibi-positive, raising the question of the clinical importance of misclassifying tumour entities with an indolent clinical course [26]. This finding could be eventually incorporated into modern active surveillance programs [27], resulting in a multimodality imaging approach concerning the non-invasive characterisation of

renal neoplasia [28] accompanied by a confirmatory renal biopsy.

The limitations of the imaging methods for accurate differentiation of Sestamibi-positive renal tumours using hybrid molecular and conventional imaging mirror the recognised diagnostic complexities of the histopathologic evaluation of this group of tumours. The expanding spectrum of oncocytic neoplasia containing mostly indolent renal entities is a grey zone that molecular imaging cannot depict. Still, mounting evidence suggests unique and distinct histopathological features of those renal tumours [15,16,29,30]. As an example of

**Figure 3.** A RO and a HOCT, both positive on  $^{99m}\text{Tc}$ -Sestamibi SPECT/CT examination. *First column, a–d:* (case n.9) SPECT axial view (a) of focal  $^{99m}\text{Tc}$ -Sestamibi uptake in the anterior aspect of the left kidney (indicated by arrow). Anatomic correlation of the previous uptake (c) in the CT study, axial view-venous phase. The axial SPECT/CT fusion image (b) with  $^{99m}\text{Tc}$ -Sestamibi uptake in the same solid renal neoplasm (12mm in maximum diameter) of the left kidney. This was subsequently diagnosed as HOCT on histopathology (d). *Second column, e–h:* (case n.13) SPECT axial view (e) displays focal  $^{99m}\text{Tc}$ -Sestamibi uptake in the upper pole of the left kidney (indicated by arrow). Anatomic correlation of the previous uptake (g) in the CT study, axial view-venous phase. The axial SPECT/CT fusion image (f) with  $^{99m}\text{Tc}$ -Sestamibi uptake in the same solid renal neoplasm (69 mm in maximum diameter) of the left kidney. This was subsequently diagnosed as RO on histopathology (h).

a distinct tumour entity with an indolent course, LOT molecular pathogenesis has been recently unravelled [15,16], encompassing mTOR pathway activation accompanied by converging mTORC1 pathway mutations and a distinctive gene expression signature. To extend, the morphological spectrum of LOT is now expanded with oncocytic renal tumours with oncocytoma-like morphological traits displaying diffuse cytokeratin 7 immunorexpression and frequent alterations in the TSC/mTOR pathway [31].

A noteworthy observation is that 3 of 11 chRCCs were reclassified as LOTs upon expert review, and these 3 tumours were all classified as Sestamibi-positive. Our findings suggest

that Sestamibi-positive renal tumours are of low malignant potential and thus, could be considered in active surveillance programs, utilising renal biopsy and longer-term imaging follow-up. The emerging question, however, concerns the diagnostic accuracy and the inherent limitations of the biopsy obtained from Sestamibi-positive renal tumours. In the current study, 4 cases diagnosed initially as RO were reclassified either as HOCT or chRCC, following a combined morphological and immunohistochemical assessment of three biopsies and one resection. These reclassifications are consistent with the findings from a systematic review and meta-analysis, suggesting that core biopsy can often be unreliable for

diagnosing RO [32]. The diagnosis on renal biopsy can be problematic also due to possible tumour heterogeneity, which is another limitation of our study since 21 tumour diagnosis of our material was based on biopsies. For this reason, many pathologists do not even issue a definitive diagnosis of RO on biopsy. Patel et al. demonstrated that 1 in 4 RO cases was misdiagnosed, with 12.5% and 6.3% of tumours re-classified following excision, either as chRCC or HOCT [32]. One of the most challenging areas in the routine renal pathology practice is the diagnosis of tumours with overlapping or equivocal features between RO and chRCC, as well as differentiating RO and chRCC from other oncocytic renal tumours that do not completely fulfil the diagnostic criteria. However, a current consensus is that these difficult-to-classify “hybrid” oncocytic tumours have an exceedingly low risk of metastatic disease [12].

Immunohistochemistry plays a major role in renal tumour diagnostics due to its widespread availability; a panel comprising cytokeratin 7 (CK7)/carbonic anhydrase IX (CAIX)/alpha-methyl acyl-CoA racemase (AMACR)/KIT (CD117) may be used for screening [33]. Other emerging markers such as FOXI1, RHCG, and LINC01187 that appear lineage-specific for renal epithelial neoplasms arising from intercalated cells in the distal nephron segment, may also play a role in the future [34]. Nevertheless, immunohistochemistry limitations are well known in routine practice, and slight differences in the immunohistochemical profiles have also been identified among HOCT subtypes (i.e. Birt-Hogg-Dubé syndrome, renal oncocytosis/oncocytomatosis and sporadic tumours) [35]. Other approaches to potentially identify unique oncocytic tumour-specific features include (i) whole scale approach of computer-assisted morphometry [36], (ii) molecular genetic approaches, including gene expression, microRNA, single-nucleotide polymorphism (SNP), array comparative genomic hybridisation (array-CGH) profiling analyses [37,38] as well as the recently proposed oncocytic nine gene classifier by McGillivray et al. [39] and (iii) an in-situ metabolomic approach [40].

These limitations, both on imaging and histopathology grounds, might explain the performance differences between the visual and the semiquantitative evaluation of the  $^{99m}\text{Tc}$ -Sestamibi SPECT/CT examination. Our work, however, adds value to a growing number of publications indicating that most ROs are Sestamibi-positive [23]. Patients with Sestamibi-positive renal tumours could avoid or postpone surgical treatment. A renal biopsy could be preferred in this patient group, as well as a longer follow-up period to track the dynamics of the examined renal neoplasms. The information derived from  $^{99m}\text{Tc}$ -Sestamibi SPECT/CT, followed by a core tissue renal biopsy, can reduce not only the overtreatment of benign renal tumours but can also reduce the proportion of untreated malignant renal tumours. The  $^{99m}\text{Tc}$ -Sestamibi SPECT/CT accompanied by a minimally invasive renal biopsy may be useful in clinical practice as a diagnostic tool to identify several indolent or low-malignant potential renal tumours, such as RO, LOT, HOCT and a subset of chRCC [41].

In conclusion, semiquantitative evaluation with SUV SPECT measurements on the renal tumour and the non-tumoral renal parenchyma did not improve the visual assessment of

$^{99m}\text{Tc}$ -Sestamibi SPECT/CT examination in characterising benign RO and differentiating it from malignant renal tumours. Visual evaluation of  $^{99m}\text{Tc}$ -Sestamibi SPECT/CT identified a group of mostly indolent Sestamibi-positive tumours containing RO, LOT (i.e. a new, emerged renal entity with no proven recurrence or metastatic potential), HOCT and a subset of chRCC. Our results suggest that patients with Sestamibi-negative renal tumours should be considered for surgery. In contrast, patients with Sestamibi-positive renal tumours could be better suited for biopsy and follow-up, according to the current active surveillance protocols.

### Ethics approval and consent to participate

This study was approved by the Regional Ethical Review Board and by the local Radiation Safety Committee (Reference no. 2015/923-31/4). Written informed consent was required from all study participants.

### Disclosure statement

The authors declare no competing interests.

### Authors contributions

AT, RA initiated and designed the study. AT, TP, OG, SG, KT, LE-E, AA, MH, MK, RA evaluated data. AT, AA, GK organised data. AT wrote the first draft, and all authors revised the manuscript critically.

### Funding

This study was financially supported by Sweden's innovation agency VINNOVA as part of the Molecular Imaging for Differentiation of Oncocytomas from Renal cancer (MIDOR) study (Reference nr. 2015-0180). Hermes Medical Solutions AB Stockholm, Sweden, provided the software used for the evaluation of SPECT/CT images.

### ORCID

Antonios Tzortzakakis  <http://orcid.org/0000-0001-7563-732X>
